MAYO CLINIC

Paraneoplastic Neurologic Syndromes: A Contemporary Approach to Diagnosis and Management

Divyanshu Dubey, MD, FAAN, FANA
Professor of Neurology
Professor of Laboratory Medicine & Pathology
Consultant and Co-Director, Neuroimmunology Laboratory
Mayo Clinic, Rochester, MN

DISCLOSURES

- KLHL11 patent licensed as a marker of neurological autoimmunity and testicular germ cell tumor.
- Patent pending for LUZP4, SKOR2 and Cavin-4 as a marker of neurological autoimmunity
- Consulted for UCB, Immunovant, Argenx, Arialys and Astellas. All compensation for consulting activities is paid directly to Mayo Clinic.
- Received funding from UCB, DOD for immunoprofiling/biomarker identification of germ cell tumors (CA210208), inflammatory neuropathies (PR220430) and ALS (AL240239).
- Discuss off label use of immunotherapy for paraneoplastic disorders.

LEARNING OBJECTIVES

Upon conclusion of this activity, participants should be able to:

- Utilize updated paraneoplastic neurological syndrome diagnostic criteria
- Determine the utility of growing repertoire of autoantibody biomarkers in the diagnosis of paraneoplastic neurological syndrome

Während die moderne Pathologie für viele Erkrankungen des Nervensystems, deren Grundlage unbekannt war, den Nachweis eines charakteristischen anatomischen Befundes führen konnte, haben uns andererseits gerade die letzten Jahre wiederum eine Reihe von Einzelbeobachtungen vor Augen geführt, in denen das mehr oder weniger scharf umschriebene Symptomenbild bestimmte pathologisch-anatomische Veränderungen mit Sicherheit erwarten liess, die trotz sorgfältigster Untersuchung vermisst wurden.

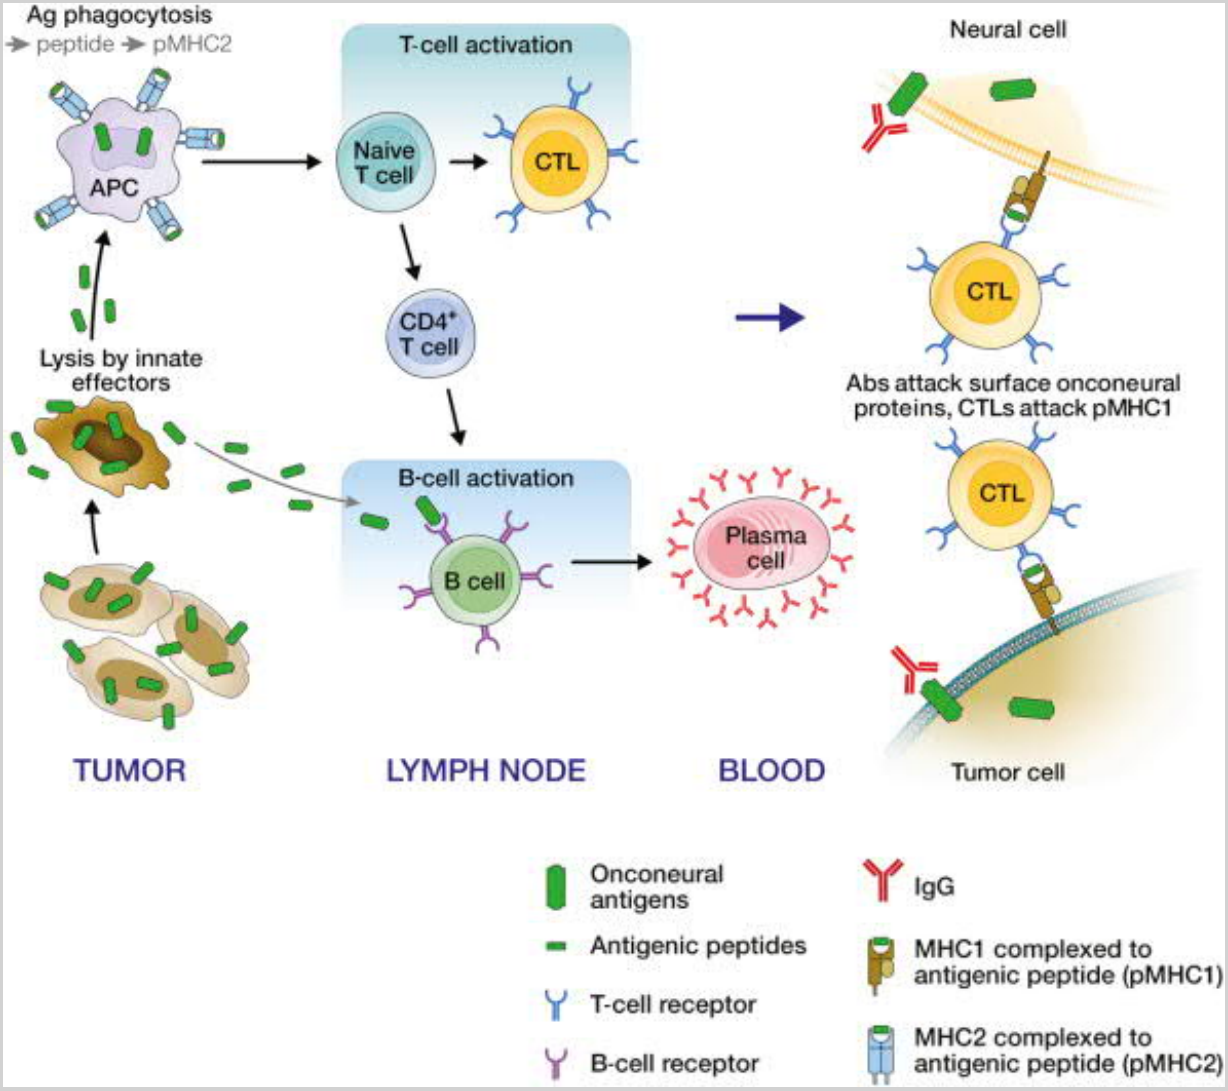
Pathophysiology



Identification of Delta/Notch-like Epidermal Growth Factor-Related Receptor as the Tr Antigen in Paraneoplastic Cerebellar Degeneration

Esther de Graaff, PhD,[1,2,3] Peter Maat, MD,[2] Esther Hulsenboom, BSc,[2] Robert van den Berg, MSc,[1,3] Martin van den Bent, MD, PhD,[2] Jeroen Demmers, PhD,[4] Pieternella J. Lugtenburg, MD, PhD,[5] Casper C. Hoogenraad, PhD,[1,3] and Peter Sillevis Smitt, MD, PhD[2]

Objective: Anti-Tr is among the better described autoantibodies in paraneoplastic cerebellar degeneration (PCD) combined with Hodgkin lymphoma (HL); however, the Tr antigen remains unidentified.
Methods: We used immunoprecipitation of total rat brain extract followed by mass spectrometry to identify the antigen recognized by anti-Tr–positive sera. By Western blotting and cell-based assays, we tested a total of 12 anti-Tr–positive and 246 control sera and determined the region of the epitope recognized by the anti-Tr antibodies. Deletion and mutant constructs were generated to further map the antigenic region.
Results: Mass spectrometry analysis of immunopurified rat brain extract using 4 different anti-Tr–positive sera led to the identification of Delta/Notch-like epidermal growth factor-related receptor (DNER) as the Tr antigen. All but 1 of 246 control samples were negative in the HeLa cell-based screening assay, whereas 12 of the 12 anti-Tr–positive sera stained hemagglutinin-tagged DNER-expressing cells. Only 1 control subject with HL but no ataxia was found to be both DNER and Tr positive. Using deletion constructs, we pinpointed the main epitope to the extracellular domain. Knockdown of endogenous DNER in hippocampal and N-glycosylation mutations abolished the anti-Tr staining, indicating that glycosylation of DNER is required for it to be recognized by anti-Tr antibodies.
Interpretation: DNER is the antigen detected by anti-Tr–positive sera. Presence of anti-Tr antibodies in patients with PCD and HL or HL only can now be screened quickly and reliably by using a cell-based screening assay.

Summary

Background Stiff-person syndrome (SPS) with antibodies to amphiphysin is a paraneoplastic disorder of the central nervous system with a putative autoimmune pathogenesis. Proof of a causal role of the antibodies is still lacking for this and all other antibody-associated paraneoplastic syndromes of the central nervous system.

Methods We obtained the plasma filtrate of a patient with breast cancer and SPS that responded to therapeutic plasmapheresis. The purified IgG fraction included high-titre antibodies to the synaptic protein amphiphysin. In a cotransfer design, this IgG fraction was injected intraperitoneally into female Lewis rats that had received encephalitogenic T-helper (Th) lymphocytes specific for myelin basic protein, to induce an immune-mediated leaky blood–brain barrier. The rats were followed up with behavioural tests, video photography, and electromyography.

Findings The injection of the IgG fraction including antibodies to amphiphysin resulted in a dose-dependent stiffness with spasms resembling human SPS. Control IgG injected into rats that had received the same encephalitogenic Th cells had no effect. IgG binding was demonstrated in the central nervous system of rats that showed signs of the disorder.

Interpretation These experiments support the hypothesis of a pathogenetic role of antibodies to amphiphysin, thus adding paraneoplastic SPS to the group of antibody-mediated autoimmune disorders.

Rat 1 and 3 received high titre anti-amphiphysin antibodies whereas rat 8 received antibodies from the control patient.

Type IIa ('anti-Hu') antineuronal antibodies produce destruction of rat cerebellar granule neurons in vitro

Immunization with the paraneoplastic encephalomyelitis antigen HuD does not cause neurologic disease in mice

P.A.E. Sillevis Smitt, MD; G.T. Manley, PhD; and J.B. Posner, MD

Article abstract—Paraneoplastic encephalomyelitis/paraneoplastic sensory neuronopathy (PEM/PSN) associated with small cell lung cancer is characterized by high serum and CSF titers of anti-neuronal (anti-Hu) antibodies and by intrathecal synthesis of anti-Hu IgG. A pathologic role for the anti-Hu antibodies in PEM/PSN is further suggested by reported intraneuronal accumulation of the antibodies in the nervous system of PEM/PSN patients at autopsy. We immunized SJL/J mice, Lewis rats, and Hartley guinea pigs with purified recombinant HuD fusion protein. In spite of high-titer anti-HuD antibodies, neurologic and pathologic examination of the animals was normal. Apparent uptake of purified IgG by neurons in the brain proved to be artifactual.

Updated PNS criteria

- Substitute “classical syndromes” with the term “high-risk phenotypes” for cancer
- Introduce the concept of “intermediate-risk phenotypes”
- “Onconeural antibody” was replaced by
  - “high risk” (>70% associated with cancer) antibodies
  - “intermediate risk” (30%–70% associated with cancer) antibodies
- Three levels of evidence for PNS by using the PNS-Care Score: definite, probable, and possible.
- Factors: clinical phenotype, antibody type, presence or absence of cancer, and time of follow-up.

PNS Care score

	Points
Clinical level	
High-risk phenotypes	3
Intermediate-risk phenotypes	2
Defined phenotype epidemiologically not associated with cancer	0
Laboratory level[a]	
High-risk antibody (>70% cancer association)	3
Intermediate risk antibody (30%–70%)	2
Lower risk antibody (<30%) or negative	0
Cancer	
Found, consistent with phenotype and (if present) antibody, or not consistent but antigen expression demonstrated	4
Not found (or not consistent) but follow-up <2 y	1
Not found and follow-up ≥2 y	0

Diagnostic level
Definite ≥8
Probable 6–7
Possible 4–5
Non-PNS ≤3

Abbreviation: PNS = paraneoplastic neurologic syndrome.

Neurol Neuroimmunol Neuroinflamm 2022;9:e1124. doi:10.1212/NXI.0000000000001124

Abstract

Objectives

Population-based epidemiologic data for paraneoplastic neurologic syndromes (PNSs) in the United States are lacking. Our objective was to evaluate the incidence, prevalence, and associated morbidity of PNS.

Methods

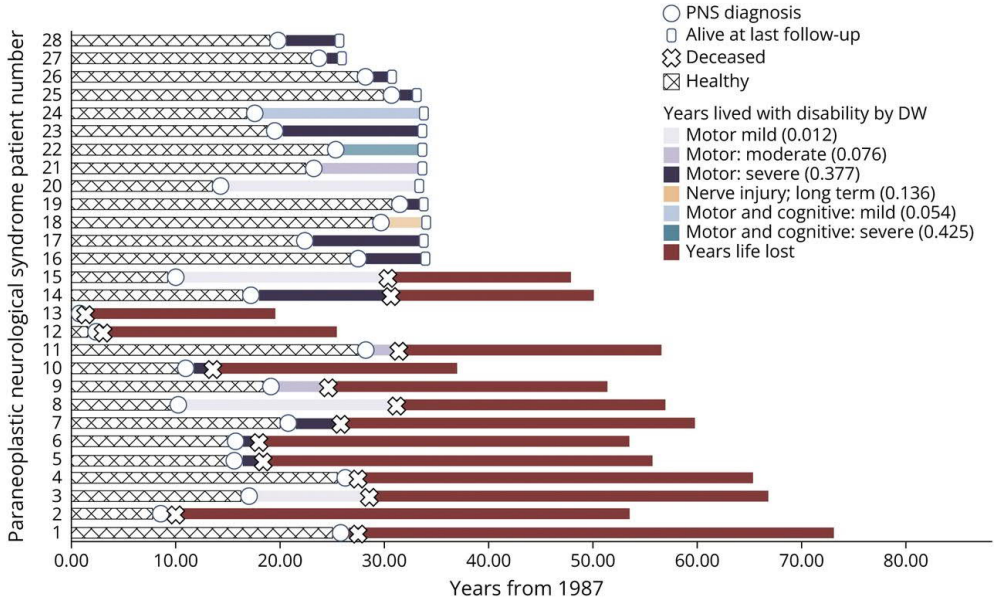
We performed a population-based epidemiology study in Olmsted County, Minnesota, with patients identified between January 1, 1987, and December 31, 2018, using the medical records linkage system of the Rochester Epidemiology Project (REP) who met the definite/probable 2021 PNS criteria and 2004 PNS criteria. Patients with dermatomyositis and myasthenia gravis with underlying tumors were included. Age- and sex-specific population counts were obtained from REP resources for January 1, 2014 (prevalence denominator) and annually for 1987–2018 (incidence denominator). Morbidity was estimated using disability-adjusted life years (DALYs; years lived with disability [YLD] plus years of life lost [YLL]).

Results

There were 28 patients with PNS identified (50% female) residing in Olmsted County, Minnesota, with median age at diagnosis of 54.5 (IQR 46.5–69.0) years. All patients had a cancer diagnosis, and 18 (64%) patients were neural autoantibody positive including antineuronal nuclear autoantibody type 1 (ANNA-1/anti-Hu; n = 1), ANNA-2/anti-Ri (n = 1), muscle-type acetylcholine receptor (AChR; n = 6), Purkinje cell cytoplasmic antibody type 1 (PCA-1/anti-Yo; n = 1), kelch-like protein 11 (KLH11; n = 3), collapsin response mediator protein 5 (CRMP-5/anti-CV2; n = 2), a-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid receptor (n = 1), neurofilament light chain (n = 1), leucine zipper 4 (LUZP4; n = 1), and unclassified neural antibodies (n = 1). PNS incidence was 0.6/100,000 person-years and increased over time from 0.4/100,000 person-years (1987–2002) to 0.8/100,000 person-years (2003–2018) ($p = 0.06$). Prevalence was 5.4/100,000 people. The median follow-up period after PNS diagnosis was 3.1 years (IQR, 1.1–9.9 years). Total disability-adjusted life years (DALYs) for 28 patients with PNS were 472.7 years, based on total years of life lost (YLL) for patients dying between 1987 and 2018 (n = 15) of 445.3 years plus years lived with disability (YLD) 27.4 years.

Discussion

PNSs are rare neurologic disorders but are associated with severe morbidity and mortality. The estimated number of prevalent PNS cases in the United States is 17,099, and predicted DALY for all US PNS cases is 292,393 years. Their apparent increasing rate of detection is attributable to increasing physician awareness and availability of serologic testing.



High risk antibodies (>70% cancer association)	Intermediate risk antibodies (30%-70% cancer association)	Low risk antibodies (<30% cancer association)
ANNA1(Anti-Hu)	AMPAR	mGluR1

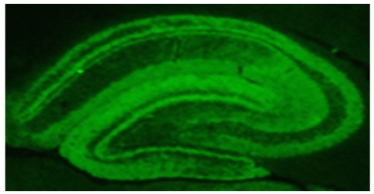
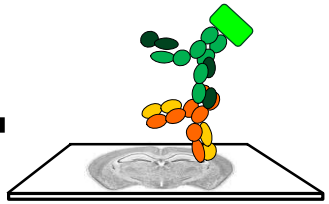
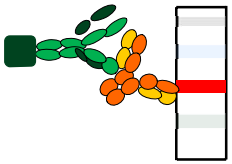
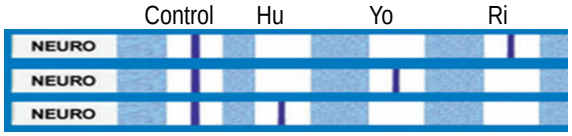
SIX TECHNIQUES FREQUENTLY USED TO DETECT ANTIBODIES IN AUTOIMMUNE NEUROLOGY



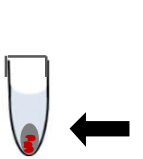
(A) Indirect immunohistochemistry

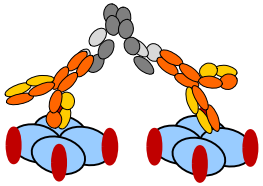




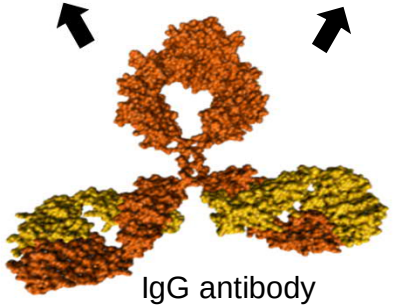


(B) Western or line blot

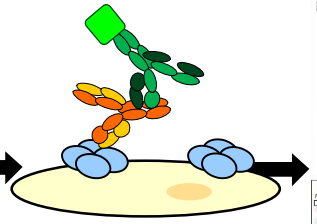


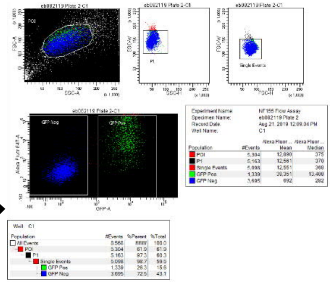


(C) Immunoprecipitation

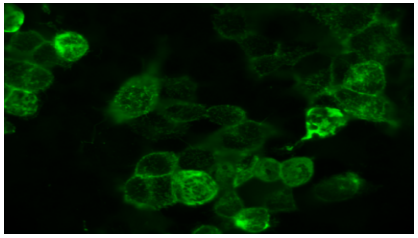


IgG antibody

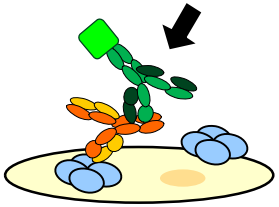


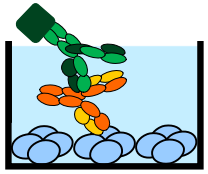


(D) Flowcytometry

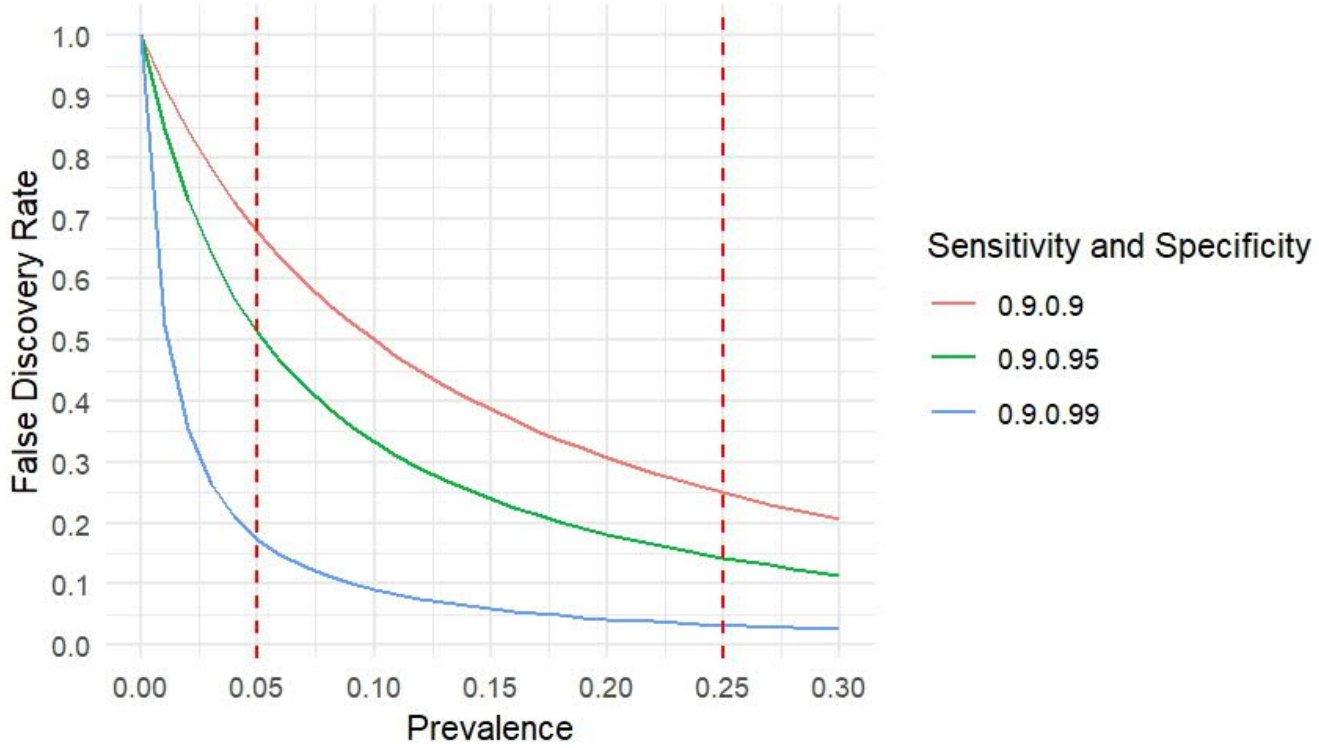


(E) Cell based assay/Flow cytometry





(F) ELISA



False discovery rate x disease prevalence

- Illustration of the relationship between false discovery rate (i.e., proportion of false positive tests) and disease prevalence:
  - blue: sensitivity 90%, specificity 99%;
  - green: sensitivity 90%, specificity 95%;
  - red: sensitivity 90%, specificity 90%.
- Notice the relatively *high false discovery rates with lower disease prevalences*, despite high assay specificities, in comparison to higher disease prevalence.
- Notice the *higher impact small changes in specificity have on false discovery rate in low prevalence* settings.
